

NPX & SASS GUIDE

1. What is npx?

npx (Node Package Execute) is a tool that comes with Node.js.

It allows you to run npm packages without installing them globally.

Key Points:

- No global installation needed
- Executes packages directly
- Uses latest version automatically

Example:

```
npx create-react-app my-app
```

2. Sass Example with npx

Step 1: Create SCSS file (style.scss)

```
$primary-color: blue;
```

```
body {
```

```
background-color: $primary-color;
```

```
}
```

Step 2: Compile using npx

```
npx sass style.scss style.css
```

Output (style.css):

```
body {
```

```
background-color: blue;
```

```
}
```

3. Watch Mode (Auto Compile)

```
npx sass --watch style.scss style.css
```

This automatically recompiles when file changes.

4. Sass for Entire Folder

You can compile a full folder instead of a single file.

Example:

```
npx sass scss:css
```

Explanation:

- "scss" = input folder
- "css" = output folder

All SCSS files inside the folder will be compiled to CSS.

5. Watch Entire Folder

```
npx sass --watch scss:css
```

Now every SCSS file inside the folder updates automatically.

Summary:

- npx = run packages without installing
- Sass = CSS preprocessor
- Useful for fast setup and development workflows
